

GOVERNMENT OF THE DISTRICT OF COLUMBIA
Department of Energy and Environment

MEMORANDUM

TO: District of Columbia Stakeholders

FROM: Hamid Karimi 
Deputy Director, Natural Resources Administration

DATE: November 28, 2017

SUBJECT: Updated Errata for the 2013 Stormwater Management Guidebook

Attached are clarifications of issues that stakeholders or the Department of Energy and Environment (DOEE) have noted in the 2013 Stormwater Management Guidebook (2013 SWMG). The 2013 SWMG provides technical guidance on compliance with the 2013 Rule on Stormwater Management and Soil Erosion and Sediment Control (2013 SW Rule), which was published as final in the *D.C. Register* on July 19, 2013.

This document is an update to the errata published on December 23, 2014. Page 1 briefly identifies the new entries. The full list of errata begins on page 2. Entries are organized by the page number where the original text is located in the 2013 SWMG and include an explanation of the reason for the change and the date of publication to this document. Each entry is designated as an omission or an edit. An omission (denoted as O) publishes clarifying information that was inadvertently excluded from the original document. An edit (denoted as E) is a substitution or deletion to clarify original intent or improve consistency.

DOEE will continue to update these errata as issues surface that require clarification and post the updated version at doee.dc.gov/swregs. DOEE will also send notifications about updates to its stormwater management email list. To be added to this list, please email Matt Johnson at matt.johnson2@dc.gov (and mention stormwater management listserv).

DOEE anticipates republishing the entire SWMG in 2018 and will include posted omissions and edits as well as any additional revisions. When republishing the entire SWMG, DOEE will notify the public through the stormwater management email list and the *D.C. Register*, and DOEE will provide an opportunity for public comment.

Errata for the 2013 Stormwater Management Guidebook

New Entries

For more detail, see the errata entries for these items.

Description	Page	Date Published	Type
Revised Contributing Drainage Area limits for green roofs.	30	11/17/17	E
Clarified that green roofs need not have separate drainage and growing media layers.	34	11/17/17	E
Added language to address solar panels and other structures atop green roofs.	35	11/17/17	E
Clarified retention value for permanently irrigated green roofs.	37	11/17/17	E
Clarified retention value for permanently irrigated green roofs.	40	11/17/17	E
Revamped bioretention filter media specifications.	107	11/17/17	E
Revised recommendations regarding BMPs in floodplains.	263	11/17/17	E
Added falling head infiltration test and associated hydraulic conductivity conversion equation	O-3	11/17/17	E

Errata

Entries are organized by the page number where the original text is located in the 2013 Stormwater Management Guidebook that is currently posted on DDOE’s website at <http://ddoe.dc.gov/swregs>.

Each entry includes an explanation of the reason for the change and the date of publication to this document. Each entry is designated as an omission or an edit. An omission (denoted as **O**) publishes clarifying information that was inadvertently excluded from the original document. An edit (denoted as **E**) is a substitution or deletion to clarify original intent or improve consistency.

Note: Due to formatting limitations with the equation software, all edits to equations are shown as full revisions instead of strikethroughs and underlines and use a black font color instead of green.

Chapter 3			
<p>Section 3.2.1 Green Roof Feasibility Criteria</p> <p>Update the Contributing Drainage Area subsection.</p> <p>Contributing Drainage Area. It is recommended that the entire contributing drainage area to a green roof (including the green roof itself) be no more than 25 percent larger than the area of <u>be limited to the green roof itself.</u> For example, a 1,000-square-foot green roof should have no more than 250 square feet of additional impervious cover draining to it. In cases where there will be additional contributing drainage area exceeds this threshold, the designer must provide supporting documentation of rooftop loading, <u>sufficient design to distribute detail showing distribution of this additional runoff throughout the green roof and area to prevent erosion or overloading of the roof surface growing media with the use of level spreaders, splash pads, perforated piping, or other flow dissipation techniques, and justification for incorporating a sizable external drainage area to the green roof.</u> The absolute maximum contributing area to a green roof shall be no more than 100% larger than the area of the green roof (e.g., a 1,000-square-foot green roof can have no more than 1,000 square feet of additional impervious cover draining to it).</p> <p>The revisions to the Contributing Drainage Area subsection are intended to address problems in design and performance that have been observed in green roofs that have significant input of runoff from external areas. The revisions</p> <ul style="list-style-type: none"> • Clarify that the preferred design for green roofs does not include contributing drainage area, • Provide more detail on the types of flow dissipation that will be required for green roofs that do have additional contributing drainage area, and • Put an upper limit on allowable additional contributing drainage area. 	O	11/17/17	E

Chapter 3 (continued)					
<p>Section 3.2.4 Green Roof Design Criteria Update the second-to-last row of Table 3.1.</p> <table border="1" data-bbox="205 451 1524 743"> <tr> <td data-bbox="205 451 506 743">Growth Media</td> <td data-bbox="506 451 1524 743">70% to 80% lightweight inorganic materials and a maximum of 30% organic matter (e.g., well-aged compost). Media typically has a maximum water retention of approximately 30%. Material makeup and proof of maximum water retention of the growing media must be provided. Media must provide sufficient nutrients and water holding capacity to support the proposed plant materials. Determine acceptable saturated water permeability using ASTM E2396-05. <u>An acceptable emerging industry practice combines the drainage layer with the growing media layer.</u></td> </tr> </table> <p>The sentence regarding combining the drainage layer with the growing media layer is added to clarify that green roofs are not required to have both a drainage layer and a growing media layer.</p>	Growth Media	70% to 80% lightweight inorganic materials and a maximum of 30% organic matter (e.g., well-aged compost). Media typically has a maximum water retention of approximately 30%. Material makeup and proof of maximum water retention of the growing media must be provided. Media must provide sufficient nutrients and water holding capacity to support the proposed plant materials. Determine acceptable saturated water permeability using ASTM E2396-05. <u>An acceptable emerging industry practice combines the drainage layer with the growing media layer.</u>	34	11/17/17	E
Growth Media	70% to 80% lightweight inorganic materials and a maximum of 30% organic matter (e.g., well-aged compost). Media typically has a maximum water retention of approximately 30%. Material makeup and proof of maximum water retention of the growing media must be provided. Media must provide sufficient nutrients and water holding capacity to support the proposed plant materials. Determine acceptable saturated water permeability using ASTM E2396-05. <u>An acceptable emerging industry practice combines the drainage layer with the growing media layer.</u>				
<p>Section 3.2.4 Green Roof Design Criteria Add the subsection “Solar Panels and Other Structures” immediately before the “Green Roof Sizing” subsection.</p> <p><u>Solar Panels and Other Structures</u></p> <p><u>Occasionally, structures such as solar panels or HVAC systems must be installed above a green roof. These structures can be incorporated into a green roof design with no adverse effects to the retention value assigned to the green roof if specific design requirements for runoff disbursement, maintenance access, and sun/wind exposure are incorporated, including the following:</u></p> <ul style="list-style-type: none"> ▪ <u>Structures above the green roof must be no more than 3.25 feet wide.</u> ▪ <u>Structures must have a minimum 3-foot separation between them.</u> ▪ <u>The lower edge of the structure must be at least 1 foot above the top of the green roof, and the upper edge must be at least 2.5 feet above the top of the green roof.</u> 	35	11/17/17	E		

Description of Change	Page	Date Published	Type
<p>These design requirements are illustrated in Figure 3.2.</p>  <p>Figure 3.2: Design Requirements for structures constructed above green roofs.</p> <p>The “Solar Panels and Other Structures” subsection is added to describe how shaded green roofs will be accommodated in the Guidebook. DOEE determined that, while it is possible that shading may reduce evapotranspiration in green roofs, there is not enough available research to justify a reduction in green roof retention value for shaded roofs at this time. As more research becomes available, the retention value for shaded green roofs will be re-examined.</p>

<p>Section 3.2.5: Green Roof Landscaping Criteria</p> <p>Delete the first two sentences in the sixth bullet and replace them with a new bullet immediately below.</p> <ul style="list-style-type: none"> <li data-bbox="191 462 1507 748"> ▪ When appropriate species are selected, most green roofs will not require supplemental irrigation, except for temporary irrigation during drought or initial establishment. The design must provide for temporary, manual, and/or permanent irrigation or watering systems, and the use of water efficient designs and/or use of non-potable sources is strongly encouraged. The planting window extends from the spring to early fall; although, it is important to allow plants to root thoroughly before the first killing frost. Green roof manufacturers and plant suppliers may provide guidance on planting windows as well as winter care. Proper planting and care may also be required for plant warranty eligibility. <li data-bbox="191 771 1507 1057"> ▪ <u>When appropriate species are selected, most green roofs will not require supplemental irrigation, except for temporary irrigation during drought or initial establishment. The use of water efficient designs and/or use of non-potable sources is strongly encouraged. Permanent irrigation of extensive roof designs is prohibited. For intensive roofs, permanent irrigation may be included. However, permanent irrigation can adversely impact the rainfall retention capacity of the green roof. For this reason, soil moisture monitors are a required part of the irrigation system for all irrigated green roofs, and the calculated retention value for green roofs with permanent irrigation must be reduced by 50%.</u> <p>Since an irrigated green roof will inherently have less storage space available than an unirrigated green roof, DOEE cannot reasonably expect a green roof with permanent irrigation to achieve the same performance level as a green roof without permanent irrigation. A number of projects have proposed to plant green roofs with species that are not drought tolerant and with permanent irrigation installed. Assigning the full retention value that would normally be used would not be consistent with the performance standard identified in the Municipal Separate Storm Sewer System (MS4) Permit issued to the District by EPA or with Chapter 5 of Title 21 of the District of Columbia Municipal Regulations. To be consistent with those performance standards and provide clarity about the appropriate retention value for a green roof with permanent irrigation, the bullet regarding irrigation is revised to more accurately account for the reduced retention benefit provided by permanently irrigated green roofs.</p>	37	11/17/17	E

Chapter 3 (continued)			
<p>Section 3.3 Rainwater Harvesting</p> <p>Definition. Rainwater harvesting systems store rainfall and release it for future use. Rainwater that falls on a rooftop or other impervious surface is collected and conveyed into an above- or below-ground tank (also referred to as a cistern), where it is stored for non-potable uses or for on-site disposal or infiltration as stormwater. Cisterns can be sized for commercial as well as residential purposes. Residential cisterns are commonly called rain barrels. <u>The design includes:</u></p> <p><u>R-1 Rainwater harvesting for non-potable uses</u></p> <p>Non-potable uses of harvested rainwater may include the following:</p> <ul style="list-style-type: none"> ▪ Landscape irrigation, ▪ Exterior washing (e.g., car washes, building facades, sidewalks, street sweepers, and fire trucks), ▪ Flushing of toilets and urinals, ▪ Fire suppression (i.e., sprinkler systems), ▪ Supply for cooling towers, evaporative coolers, fluid coolers, and chillers, ▪ Supplemental water for closed loop systems and steam boilers, ▪ Replenishment of water features and water fountains, ▪ Distribution to a green wall or living wall system, <u>and</u> ▪ Laundry, and, ▪ Delayed discharge to the combined sewer system. <p>Add “The design includes: R-1 Rainwater harvesting for non-potable uses” to create consistent codes for incorporating the General Retention Compliance Calculator in DDOE’s new Stormwater BMP Tracking Database. Also, relocate “and” and remove “Delayed discharge to the combined sewer system.” to be consistent with the categories in the Rainwater Harvesting Retention Calculator.</p>	43	05/01/2014	O

Accepted TSS Treatment Practice	N/A <u>=Sv</u>						
<p>Section 3.6.4 Bioretention Design Criteria</p> <p>Revise the Filter Media subsection as follows:</p> <p>Filter Media. <u>The filter media of a bioretention practice consists of an engineered soil mixture that has been carefully blended to create a soil media that maintains long-term permeability while also providing enough nutrients to support plant growth. The final filter media shall consist of a well-blended mixture of medium to coarse sand, base loam soil (soil fines), and an organic amendment (compost). The sand maintains a desired long-term permeability of the media while the limited amount of soil fines and organic amendments are considered adequate to help support initial plant growth. It is anticipated that the gradual increase of organic material through natural processes will continue to support plant growth without the need to add fertilizer, and the root structure of maturing plants and the biological activity of the media will maintain sufficient long-term permeability.</u> and surface cover are the two most important elements of a bioretention facility in terms of long-term performance.</p> <p>▪ Particle Size Composition. The bioretention soil mixture shall be classified as a loamy sand on the USDA Texture Triangle, with the following particle size composition:</p> <ul style="list-style-type: none"> ◆ 80-90 percent sand (at least 75 percent of which must be classified as coarse or very coarse sand) ◆ 10-20 percent soil fines (silt and clay) 	107	11/17/17	E				

Description of Change	Page	Date Published	Type
<p>◆ Maximum 10 percent clay</p> <p>◆ The particle size analysis must be conducted on the mineral fraction only or following appropriate treatments to remove organic matter before particle size analysis.</p> <p>◆ Organic Matter. The filter media must contain 3 to 5 percent organic matter by the conventional Walkley Black soil organic matter determination method or similar analysis. Soil organic matter is expressed on a dry weight basis and does not include coarse particulate (visible) components.</p> <p>◆ Available Soil Phosphorus (P). The filter media should contain sufficient available P to support initial plant establishment and growth, but not serve as a significant source of P for long term leaching. Plant available soil P should be within the range of Low+ (L+) to Medium (M) as defined in Table 2.2 of Virginia Nutrient Management Standards and Criteria (2005). For the Mehlich I extraction procedure this equates to a range of 5 to 15 mg/kg P or 18 to 40 mg/kg P for the Mehlich III procedure.</p> <p>◆ Cation Exchange Capacity (CEC). The relative ability of soils to hold and retain nutrient cations like Ca and K is referred to as cation exchange capacity (CEC) and is measured as the total amount of positively charged cations that a soil can hold per unit dry mass. CEC is also used as an index of overall soil reactivity and is commonly expressed in milliequivalents per 100 grams (meq/100g) of soil or cmol+/kg (equal values). A soil with a moderate to high CEC indicates a greater ability to capture and retain positively charged contaminants, which encourages conditions to remove phosphorus, assuming that soil fines (particularly fine silts and clays) are at least partially responsible for CEC. The minimum CEC of the filter media is 5.0 (meq/100 g or cmol+/kg). The filter media CEC should be determined by the Unbuffered Salt, Ammonium Acetate, Summation of Cations or Effective CEC techniques (Sumner and Miller, 1996) or similar methods that do not utilize strongly acidic extracting solutions.</p> <p>The goal of the filter media mixture described in this section is to create a soil media that maintains long term permeability while also providing enough nutrients to support plant growth. The initial permeability of the mixture will exceed the desired long term permeability of 1 to 2 in./hr. The limited amount of topsoil and organic matter is considered adequate to help support initial plant growth, and it is anticipated that the gradual increase of organic material through natural processes will continue to support growth while gradually decreasing the permeability. Finally, the root structure of maturing plants and the biological activity of a self-sustaining organic content will maintain sufficient long term permeability as well as support plant growth without the need to add fertilizer.</p>			

Description of Change	Page	Date Published	Type
<p>The following is the recommended composition of the three media ingredients:</p> <ul style="list-style-type: none"> <p>Sand (Fine Aggregate). Sand shall consist of silica-based <u>medium to coarse aggregate sand</u>, angular or round in shape and meet the mixture grain size distribution specified in Table 3.19. No substitutions of alternate materials (such as diabase, calcium carbonate, rock dust, or dolomitic sands) are accepted. In particular, mica can make up no more than 5 percent of the total sand fraction. The sand fraction may also contain a limited amount of particles greater than 2.0 mm and less than 9.5 mm per the table below, but the overall sand fraction must meet the specification containing greater than 75 percent coarse or very coarse sand. Consult Table 3.19 for recommended sand sizing criteria. <u>The materials shall not be derived from serpentine and shall be free of loam or clay, diabase, surface coatings, or any other deleterious materials and shall contain less than 0.5% mica by weight when tested with ASTM C295, Petrographic Examination of Aggregates for Concrete.</u></p> <p><u>ASTM C-33 concrete sand will typically meet the requirements for the sand to be used in filter media. However, some samples of ASTM C-33 sand may have too high a fraction of fine sand and silt- and clay-sized particles to allow the final filter media particle size distribution requirements to be met. In general, coarser gradations of ASTM C-33 will better meet the filter media particle size distribution and hydraulic conductivity requirements.</u></p> <p><u>Any other materials, such as limestone-based sands or crushed glass, shall meet the required particle size distribution and be demonstrated as adequately durable when tested by AASHTO T-103 or T-104.</u></p>

Description of Change			Page	Date Published	Type
Top Soil	Loamy sand or sandy loam	USDA Textural Triangle			
Organic Matter	Well-aged, clean compost	Appendix J			
P-Index or Phosphorus (P) Content	Soil media with high P levels will export P through the media and potentially to downstream conveyances or receiving waters	P content = 5 to 15 mg/kg (Mehlich I) or 18 to 40 mg/kg (Mehlich III)			
Cation Exchange Capacity (CEC)	The CEC is determined by the amount of soil fines and organic matter. Higher CEC will promote pollutant removal	CEC > 5 milliequivalents per 100 grams			
<p>Many specifications for sand refer to ASTM C-33. The ASTM C-33 specification allows a particle size distribution that contains a large fraction of fines (silt and clay sized particles < 0.05 mm). The smaller fines fill the voids between the larger sand sized particles, resulting in smaller and more convoluted pore spaces. While this condition provides a high degree of treatment, it also encourages clogging of the remaining void spaces with suspended solids and biological growth, resulting in a greater chance of a restrictive biomat forming. By limiting the fine particles allowed in the sand component, the combined media recipe of sand and the fines associated with the soil and organic material will be less prone to clogging, while also providing an adequate level of filtration and retention.</p> <p>In cases where greater removal of specific pollutants is desired, additives with documented pollutant removal benefits, such as water treatment residuals, alum, iron, or other materials may be included in the filter media if accepted by DDOE.</p> <p><u>Complete Filter Media.</u> The complete filter media soil mix shall consist of a pug milled or mechanically blended mix of the three source materials resulting in a filter media that meets the following particle size composition, as well as the grain size distribution indicated in Table 3.19.</p>

Description of Change	Page	Date Published	Type
<p>Significant revisions are made to the Filter Media subsection to create filter media requirements that are easier to abide by and better align with DDOT’s bioretention soil specifications. The main revisions involve less stringent sand requirements, and more focus on the particle size composition of the final product rather than the individual components. To improve legibility, a “clean” version is provided here:</p> <p>Filter Media. The filter media of a bioretention practice consists of an engineered soil mixture that has been carefully blended to create a soil media that maintains long-term permeability while also providing enough nutrients to support plant growth. The final filter media shall consist of a well-blended mixture of medium to coarse sand, base loam soil (soil fines), and an organic amendment (compost). The sand maintains a desired long-term permeability of the media while the limited amount of soil fines and organic amendments are considered adequate to help support initial plant growth. It is anticipated that the gradual increase of organic material through natural processes will continue to support plant growth without the need to add fertilizer, and the root structure of maturing plants and the biological activity of the media will maintain sufficient long-term permeability.</p> <p>The following is the recommended composition of the three media ingredients:</p> <ul style="list-style-type: none"> ▪ Sand (Fine Aggregate). Sand shall consist of silica-based medium to coarse sand, angular or round in shape. The materials shall not be derived from serpentine and shall be free of loam or clay, diabase, surface coatings, or any other deleterious materials and shall contain less than 0.5% mica by weight when tested with ASTM C295, Petrographic Examination of Aggregates for Concrete. <p>ASTM C-33 concrete sand will typically meet the requirements for the sand to be used in filter media. However, some samples of ASTM C-33 sand may have too high a fraction of fine sand and silt- and clay-sized particles to allow the final filter media particle size distribution requirements to be met. In general, coarser gradations of ASTM C-33 will better meet the filter media particle size distribution and hydraulic conductivity requirements.</p> <p>Any other materials, such as limestone-based sands or crushed glass, shall meet the required particle size distribution and be demonstrated as adequately durable when tested by AASHTO T-103 or T-104.</p>			

Description of Change	Page	Date Published	Type			
<p>▪ Base Loam Soil. Base loam soil is generally defined as the combination of sand-sized material, fines (silt and clay), and any associated soil organic matter. Since the objective of the specification is to carefully establish the proper blend of these ingredients, the designer (or contractor or materials supplier) must carefully select the topsoil source material in order to not exceed the amount of any one ingredient.</p> <p>Generally, a natural loamy sand, sandy loam, or loam (per the USDA Textural Triangle) A-horizon topsoil free of subsoil, large stones, earth clods, sticks, stumps, clay lumps, roots, viable noxious weed seed, plant propagules, brush, or other objectionable, extraneous matter or debris is suitable for the base loam (soil fines) source material.</p> <p>▪ Organic Amendments. Organic amendments shall consist of stable, well-decomposed, natural, carbon-containing organic materials such as peat moss, humus, or yard waste (consistent with the material specifications found in Appendix J. The material shall be free of debris such as plastics, metal, concrete, stones larger than 1/2 inch, larger branches and roots, and wood chips over 1 inch in length or diameter.</p> <p>Complete Filter Media. The complete filter media soil mix shall consist of a pug milled or mechanically blended mix of the three source materials resulting in a filter media that meets the following particle size composition, as well as the grain size distribution indicated in Table 3.19.</p> <ul style="list-style-type: none"> ▪ 80%–90% sand (at least 75% of which must be classified as coarse or very coarse sand) ▪ 10%–20% soil fines (silt and clay) ▪ Maximum 10% clay <p>Note: The above percentages are based on weight rather than volume. The particle size analysis must be conducted on the mineral fraction only or following appropriate treatments to remove organic matter before particle size analysis. The DDOT Green Infrastructure Standards include a bioretention soil specification based on volume, not weight, so the percentages listed there do not match those listed here, even though the two specifications are substantially equivalent.</p> <p>Table 3.17 Filter Media Grain Size Distribution</p> <table border="1" data-bbox="205 1435 1094 1482"> <thead> <tr> <th>Sieve Type</th> <th>Particle Size (mm)</th> <th>Percent Passing (%)</th> </tr> </thead> </table>	Sieve Type	Particle Size (mm)	Percent Passing (%)

<p>The filter media shall also meet the following criteria:</p> <ul style="list-style-type: none"> ▪ Organic content shall be between 3.0% and 5.0% by weight; ▪ pH shall be between 6.0 and 7.2; ▪ Cation exchange capacity (CEC) shall be a minimum of 5 meq/100g or cmol+/kg; ▪ Phosphorus content shall meet one of the following: <ul style="list-style-type: none"> ◆ P-Index between 10 and 30; ◆ 5–15mg/kg Mehlich I Extraction; ◆ 18–40mg/kg Mehlich III Extraction; and ▪ Soluble salts shall be less than 500 ppm/0.5 mmhos/cm. <p>Notes:</p> <ol style="list-style-type: none"> 1. P-Index is an agronomic test used in North Carolina to indicate the potential for P leaching from soil. The test method has been revised to add P concentration to facilitate local lab testing. The value of the P-Index is the correlation between the CEC and P concentrations: higher CEC indicates greater adsorption sites within the media, thus increasing the ability to fix P within the soil, thereby allowing higher P concentrations without leaching. While P-Index may be a better overall representation of P, the test method may not be readily available. 2. Tests for organic content, CEC, soluble salts, and pH are referenced to be in accordance with Recommended Soil Testing Procedures for the Northeastern United States, Current Edition, Northeastern Regional Publication No. 493. <p>Table 3.18 Summary of Filter Media Criteria for Bioretention</p> <table border="1"> <thead> <tr> <th>Soil Media Criterion</th> <th>Description</th> <th>Standard(s)</th> </tr> </thead> </table>						Soil Media Criterion	Description	Standard(s)
Soil Media Criterion	Description	Standard(s)						

Description of Change			Page	Date Published	Type
General Composition	Filter media must have the proper proportions of sand, fines, and organic matter to promote plant growth, drain at the proper rate, and filter pollutants.	80%–90% sand; 10%–20% soil fines; maximum of 10% clay; and 3%–5% organic matter			
Sand	Silica based coarse aggregate	Based on final filter media particle size			
Top Soil	Loamy sand or sandy loam	USDA Textural Triangle			
Organic Matter	Well-aged, clean compost	Appendix J			
P-Index or Phosphorus (P) Content	Soil media with high P levels will export P through the media and potentially to downstream conveyances or receiving waters.	P-Index of 10–30 or P content = 5 to 15 mg/kg (Mehlich I) or 18 to 40 mg/kg (Mehlich III)			
Cation Exchange Capacity (CEC)	The CEC is determined by the amount of soil fines and organic matter. Higher CEC will promote pollutant removal.	CEC > 5 milliequivalents per 100 grams			
<p>In cases where greater removal of specific pollutants is desired, additives with documented pollutant removal benefits, such as water treatment residuals, alum, iron, or other materials, may be included in the filter media if accepted by DOEE.</p>					
Chapter 3 (continued)					
Section 3.6.4 Bioretention Design Criteria			110	05/01/2014	E

Description of Change	Page	Date Published	Type
<p>▪ Filter Media Depth. The filter media bed depth must be a minimum of 18 inches for the Standard Design. The media depth must be 24 inches or greater to qualify for the Enhanced Design, unless an infiltration-based design is used. The media depth must not exceed 6.5 feet. Turf, perennials, or shrubs should be used instead of trees to landscape shallower filter beds. See Table 3.23 and Table 3.24 for a list of recommended native plants.</p> <p>Add “.5” after “6” to correspond with the updated values in Table 3.2.1 on page 111.</p>			
<p>Section 3.6.4 Bioretention Design Criteria</p> <p>During high intensity storm events, it is possible for the bioretention to fill up faster than the collected stormwater is able to filter through the soil media. This is dependent upon the surface area of the BMP (SA) relative to the contributing drainage area (CDA) and the runoff coefficient (R_v) from the CDA. To ensure that the design runoff volume is captured and filtered appropriately, a maximum filter media depth must not be exceeded (see Table 3.24). The maximum filter media depth is based on the runoff coefficient of the CDA to the BMP (R_{vCDA}) and the bioretention ratio of BMP surface area to the BMP CDA (SA:CDA) (in percent). <u>The R_{vCDA} is an average of runoff coefficients of land cover types in the BMP’s CDA. The land cover runoff coefficient types can be selected from Table H.1, Runoff Coefficient Factors for Typical District of Columbia Land Uses, or using the three categories established for calculating the SWRV (natural, compacted, and impervious cover).</u> The applicable filter media depth from Table 3.21 should be used as d_{media} in Equation 3.5. <u>Note: In the gray cells, overflow is not likely to occur for the design storm, so no maximum filter media depth is specified.</u></p> <p>Add “The R_{vCDA} is an average of runoff coefficients of land cover types in the BMP’s CDA. The land cover runoff coefficient types can be selected from Table H.1, Runoff Coefficient Factors for Typical District of Columbia Land Uses, or using the three categories established for calculating the SWRV (natural, compacted, and impervious cover).” to explain how to calculate R_{vCDA} and to refer to values provided in Table H.1. Also add “Note: In the gray cells, overflow is not likely to occur for the design storm, so no maximum filter media depth is specified.” to clarify the reason that some cells in Table 3.21 now have null values.</p>	111	05/01/2014	O

In the header of Table 3.21, remove “RvCDA” and replace with “RV _{CDA} ” to correct a typographical error. In the body of the table, remove or change several maximum filter media depth values (as indicated above), and shade the cells with null values. Further design event simulation looking at the relationship between effective storage depth and overflow supported less restrictive depths overall.												
Chapter 3 (continued)												
Section 3.6.4 Bioretention Design Criteria										112	05/01/2014	O

Description of Change	Page	Date Published	Type
<p>► Underdrains. Many bioretention designs will require an underdrain (see Section 3.6.1 Bioretention Feasibility Criteria). The underdrain should be a 4- or 6-inch perforated schedule 40 PVC pipe, or equivalent corrugated HDPE for small bioretention BMPs, with 3/8-inch perforations at 6 inches on center. The underdrain must be encased in a layer of clean, double washed ASTM D448 No.57 or smaller (No. 68, 8, or 89) stone. <u>The maximum depth for the underdrain stone layer is 12 inches.</u> The underdrain must be sized so that the bioretention BMP fully drains within 72 hours or less. ◀</p> <p>► Underground Storage Layer (optional). For bioretention systems with an underdrain, an underground storage layer consisting of chambers, perforated pipe, stone, or other acceptable material can be incorporated below the filter media layer and underdrain to increase the infiltration sump volume or the storage for larger storm events. To qualify for the Enhanced Design, this storage layer must be designed to infiltrate in 72 hours, at ½ the measured infiltration rate. The <u>underground storage layer</u> may also be designed to provide detention for the 2-year, 15-year, or 100-year storms, as needed. The depth and volume of the storage layer will then depend on the target storage volumes needed to meet the applicable detention criteria. <u>Suitable conveyance must then be provided to ensure that the storage is fully utilized without overflow of the bioretention area.</u> ◀</p> <p>Add a sentence to the “Underdrains” paragraph stating that “The maximum depth for the underdrain stone layer is 12 inches.” to align the text with revisions to Table 3.21. In the “Underground Storage Layer” paragraph, add “underground storage layer” to clarify a concept that was implied but not fully stated and add “Suitable conveyance must then be provided to ensure that the storage is fully utilized without overflow of the bioretention area.” to clarify the engineering obligation associated with this choice.</p>			
Chapter 3 (continued)			
Section 3.6.4 Bioretention Design Criteria	117	05/01/2014	O

Description of Change	Page	Date Published	Type
<p>BMP Sizing. Bioretention is typically sized to capture the SWR_v or larger design storm volumes in the surface ponding area, soil media, and gravel reservoir layers of the BMP.</p> <p>Total storage volume of the BMP is calculated using Equation 3.5a.</p> <p>Equation 3.5a Bioretention Storage Volume</p> $S_v = SA_{bottom} \times [(d_{media} \times \eta_{media}) + (d_{gravel} \times \eta_{gravel})] + (SA_{average} \times d_{ponding})$ <p>where:</p> <ul style="list-style-type: none"> S_v = total storage volume of bioretention (ft³) SA_{bottom} = bottom surface area of bioretention (ft²) d_{media} = depth of the filter media (ft) η_{media} = effective porosity of the filter media (typically 0.25) d_{gravel} = depth of the underdrain and underground storage gravel layer (ft) η_{gravel} = effective porosity of the gravel layer (typically 0.4) $SA_{average}$ = average surface area of bioretention (ft²) (typically, where SA_{top} is the top surface area of bioretention, $SA_{average} = \frac{SA_{bottom} + SA_{top}}{2}$) $d_{ponding}$ = maximum ponding depth of bioretention (ft) <p>Equation 3.5a can be modified if the storage depths of the filter media, gravel layer, or ponded water</p>			

Description of Change	Page	Date Published	Type
<p>vary in the actual design or with the addition of any surface or subsurface storage components (e.g., additional area of surface ponding, subsurface storage chambers, etc.). The maximum depth of ponding in the bioretention must not exceed 18 inches. If storage practices will be provided off-line or in series with the bioretention area, the storage practices should be sized using the guidance in Section 3.12.</p> <p><u>For enhanced bioretention areas, the volume that will be infiltrated (the sump volume for underdrained designs or the entire volume for non-underdrained designs) must infiltrate within 72 hours. Measured infiltration rates must exceed 0.1 inches per hour to qualify for the enhanced design retention value. The depth of the infiltration sump for underdrained designs can be determined using Equation 3.5b.</u></p> <p><u>Equation 3.5b Bioretention Infiltration Sump Depth</u></p> $d_{sump} = \frac{\left(\frac{i}{2} \times t_d\right)}{\eta_r}$ <p>where:</p> <p><u>d_{sump}</u> = depth of the infiltration sump (in) <u>i</u> = field-verified (actual) infiltration rate for the native soils (in./hr) (must exceed 0.1 in./hr) <u>t_d</u> = drawdown time (hr) (within 72 hr) <u>η_r</u> = available porosity of the stone reservoir (typically 0.4)</p> <p><u>For non-underdrained designs, a check must be performed to ensure that the entire S_v infiltrates within 72 hours, as in Equation 3.5c.</u></p>			

Description of Change	Page	Date Published	Type
<p>Equation 3.5c Bioretention Infiltration Rate Check</p> $Sv_{infiltrate} = \frac{SA_{bottom} \left(\frac{i}{2} \times t_d \right)}{12}$ <p>where:</p> <p>$Sv_{infiltrate}$ = storage volume that will infiltrate within 72 hours (ft³)</p> <p>SA_{bottom} = bottom surface area of bioretention (ft²)</p> <p>i = field-verified (actual) infiltration rate for the native soils (in./hr)</p> <p>t_d = drawdown time (hr) (within 72 hr)</p> <p><u>If $Sv_{infiltrate}$ is greater than or equal to Sv, then the entire Sv will infiltrate within 72 hours. If it is not, the storage volume of the bioretention area should be reduced accordingly.</u></p> <p>Change “Equation 3.5” (Bioretention Storage Volume) to “Equation 3.5a” and add Equation 3.5b Bioretention Infiltration Sump Depth and Equation 3.5c Bioretention Infiltration Rate Check, which were inadvertently omitted from the text. Before equation 3.5b, add the following explanatory text: “For enhanced bioretention areas, the volume that will be infiltrated (the sump volume for underdrained designs or the entire volume for non-underdrained designs) must infiltrate within 72 hours. Measured infiltration rates must exceed 0.1 inches per hour to qualify for the enhanced design retention value. The depth of the infiltration sump for underdrained designs can be determined using Equation 3.5b.” Before Equation 3.5c, add the following explanatory text: “For non-underdrained designs, a check must be performed to ensure that the entire Sv infiltrates within 72 hours, as in Equation 3.5c.”</p>			
Chapter 3 (continued)			
Section 3.6.6 Bioretention Construction Sequence	122	05/01/2014	E

Description of Change	Page	Date Published	Type
<p>◆ Alternatively, if it is infeasible to keep the proposed permeable pavement <u>bioretention</u> areas outside of the limits of disturbance, and excavation of the area cannot be restricted, then infiltration tests will be required prior to installation of the bioretention to ensure that the design infiltration rate is still present. If tests reveal the loss of design infiltration rates then deep tilling practices may be used in an effort to restore those rates. In this case further testing must be done to establish design rates exist before the permeable pavement can be installed.</p> <p>Remove “permeable pavement” and replace with “bioretention” to correct a typographical error.</p>			
<p>Section 3.10 Ponds</p> <p>▶</p> <p>P<u>C</u>-1 Micropool extended detention pond</p> <p>P<u>C</u>-2 Wet pond</p> <p>P<u>C</u>-3 Wet extended detention pond ◀</p> <p>▶ Stormwater ponds do not receive any<u>receive only 10%</u> stormwater retention value and should be considered only<u>mainly</u> for management of larger storm events. Appendix O			
<p>Section O.1 General Notes Pertinent to All Geotechnical Testing</p> <ul style="list-style-type: none"> ▪ Testing is to be conducted by a qualified professional. This professional shall either be a registered professional engineer, soils scientist, or geologist and must be licensed in the District of Columbia. ▪ Soil boring or test pit information is to be obtained from at least one location on the site. <u>Additional borings or test pits are required within the proposed BMP facility under three conditions: (1) when the soils or slopes vary appreciably from the findings in the initial boring or test pit, (2) when the ground water level is found to be significantly higher than initial boring or test pit indicated, and (3) when the ground water level may adversely affect the performance of the proposed BMP facilities.</u> However, the location, number, and depth of borings or test pits shall be determined by a qualified professional, and be sufficient to accurately characterize the site soil conditions. ▪ Depth to the ground water table <u>(with 24-hour readings)</u> and estimated depth to the seasonally high ground water table must be included in the boring logs/geotechnical report. ▪ Laboratory testing must include grain size analysis. Additional tests such as liquid limit and plastic limit tests, consolidation tests, shear tests and permeability tests may be necessary <u>where foundation soils or slopes are potentially unstable</u> based on the discretion of the qualified professional. ▪ The geotechnical report must include soil descriptions from each boring or test pit, and the laboratory test results for grain size. Based upon the proposed development, the geotechnical report may also include evaluation of settlement, bearing capacity and slope stability of <u>soils supporting the proposed structures.</u> <p>At the end of the first bullet, add “Additional borings or test pits are required within the proposed BMP facility under three conditions: (1) when the soils or slopes vary appreciably from the findings in the initial boring or test pit, (2) when the ground water level is found to be significantly higher than initial boring or test pit indicated, and (3) when the ground water level may adversely affect the performance of the proposed BMP facilities.” In the second bullet, add “(with 24-hour readings).” In the third bullet, add “where foundation soils or slopes are potentially unstable.” In the fourth bullet, add “soils supporting.” These additions are needed to provide greater detail on constant head test methods and process, as requested by local geotechnical consulting practitioners.</p>	O-1	05/01/2014	O

<p>Section O.3 Test Pit/Boring Requirements for Infiltration Tests</p> <ol style="list-style-type: none"> a. Excavate a test pit or drill a standard soil boring to a depth of 2 feet below the proposed facility bottom. b. Determine depth to groundwater table (if within 2 feet of proposed bottom), and the estimated seasonally high groundwater table. c. Determine Unified Soil Classification (USC) System <u>and/or United States Department of Agriculture (USDA)</u> textures at the proposed bottom and 4 feet below the bottom of the BMP. d. Determine depth to bedrock (if within 2 feet of proposed bottom). e. The soil description must include all soil horizons. <u>Perform the infiltration test at the proposed bottom of the practice.</u> If any of the soil horizons below the proposed bottom of the infiltration practice (<u>within 2 feet</u>) appear to be a confining layer, additional infiltration tests must be performed on this layer (or layers), following the procedure described below. f. The location of the test pits or borings shall correspond to the BMP locations; <u>a map or plan that clearly and accurately indicates the location(s) of the test pits or soil borings must be provided with the geotechnical report.</u> test pit/soil boring stakes are to be left in the field for inspection purposes and shall be clearly labeled as such. <p>In item c, add “and/or United States Department of Agriculture (USDA).” In item e, add “Perform the infiltration test at the proposed bottom of the practice.” and “(within 2 feet).” In item f, remove “test pit/soil boring stakes are to be left in the field for inspection purposes and shall be clearly labeled as such” and add “a map or plan that clearly and accurately indicates the location(s) of the test pits or soil borings must be provided with the geotechnical report.” These changes are needed to provide greater detail on constant head test methods and process, as requested by local geotechnical consulting practitioners.</p>	O-2	05/01/2014	O/E

<p>Section O.4 Infiltration Requirements Testing</p> <p><u>Changes on 11/17/2017:</u> Replace the Double-Ring Infiltrometer test bullet with a description of an acceptable falling head test (changes shown in red font).</p> <p>The following tests are acceptable for use in determining soil infiltration rates. The geotechnical report shall include a detailed description of the test method and published source references:</p> <ul style="list-style-type: none"> ▪ Well Permeameter Method (USBR 7300-89); <u>Constant Head Bore-Hole Infiltration Tests (also referred to as bore-hole permeameter tests and constant-head well permeameter tests). These types of tests determine saturated hydraulic conductivity (coefficient of permeability) by measuring the rate of water flow into a borehole. Analytical solutions utilize principals of Darcy's Law, borehole geometry, and head, or multiple heads, of water in determining saturated hydraulic conductivity. Infiltration rate is determined utilizing Darcy's Law and observations of soil characteristics. Where the soil characteristics meet all of the above-described requirements for infiltration BMPs, the hydraulic gradient element of Darcy's Law is often estimated as 1 for determining infiltration rate.</u> <p><u>One published standard developed by the United States Bureau of Reclamation for this method is USBR 7300-89. Some of the commercially available equipment is listed below:</u></p> <ul style="list-style-type: none"> ◆ <u>Amoozemeter</u> ◆ <u>Guelph Permeameter</u> ◆ <u>Johnson Permeameter</u> <p>▪ Tube Permeameter Method (ASTM D 2434);</p>	O-3	05/01/2014 revised on 11/17/2017 (new text in red)	O/E

Description of Change	Page	Date Published	Type
<p>■ Double Ring Infiltrometer (ASTM D 3385). This test method measures the rate of water infiltration into soil utilizing two concentric rings to pond water at a controlled depth at the top of the natural soil of the test area. The downward loss of water from the inner ring determines the infiltration rate while the downward loss of water from the outer ring compensates for lateral loss to the soil from the inner ring that would otherwise occur from a single ring. The details of this method, including the minimum specified diameter of the rings, must be strictly adhered to in order to maintain integrity of the test results.</p> <p>This test method requires that both concentric rings be placed simultaneously into the upper few centimeters of the natural soil. In some cases, significant excavation is required to prepare a working area at the desired elevation.</p> <p>■ Other constant head permeability tests that utilize in-situ conditions and are accompanied by a peer reviewed source reference.</p> <p>■ <u>Maryland Stormwater Design Manual, Appendix D.1 Testing Requirements for Infiltration, Bioretention, and Sand Filter Subsoils, as modified below. The data obtained from this infiltration testing procedure shall be used to calculate the saturated hydraulic conductivity (see Section O.5).</u></p> <ol style="list-style-type: none"> 1. <u>Install solid casing in the boring or test pit to the proposed BMP bottom or other required test depth (i.e., confining layer encountered within 2 feet below the BMP bottom). When installing casing, drive the casing between 3 to 5 inches below the test surface to promote good casing-to-soil seal.</u> 2. <u>Remove any smeared, soiled surfaces, and provide a natural soil interface into which water may infiltrate. Remove all loose material from the casing. At the tester's/registered professional's discretion, a 2-inch layer of coarse sand or fine gravel may be placed to protect the bottom from scouring and sediment. Fill the casing with clean water 24 inches above the test surface (24 inches of head), and allow to presoak for 24 hours.</u> 3. <u>Protect the open borehole with suitable cover such as a sanitary well cap and steel plate with surrounding sandbags to prevent the introduction of surface water runoff, trash, debris, and other pollutants.</u> 			

Description of Change	Page	Date Published	Type
<p>4. <u>Twenty-four hours later, refill the casing with approximately 24 inches of clean water (24 inches of head), and monitor water level for 1 hour, recording the depth of water at the beginning and end of the test.</u></p> <p><u>Repeat step 4 (filling the casing each time) three additional times, for a total of four observations. At the registered professional’s discretion, the saturated hydraulic conductivity calculations may be performed based on the values recorded during the average of the four readings or the last observation. The testing interval can be increased at the discretion of the registered professional.</u></p> <p><u>All soil borings and test pits shall be properly backfilled after conclusion of tests.</u></p> <p>An infiltration test does not require groundwater quality protection approval if</p> <ul style="list-style-type: none"> ▪ <u>The test is conducted to a depth of fifteen feet or less below the ground surface, and</u> ▪ <u>A Professional Engineer licensed in the District of Columbia certifies the infiltration ratehydraulic conductivity and that the test was carried out in compliance with this guidance and accepted professional standards.</u> <p>Note: If the infiltration testing procedure reveals smells or visual indications of soil or groundwater contamination then the boring or test hole must be filled in accordance with wellhead protection best practices, unless laboratory analysis determines groundwater or soil is not contaminated, as defined in the District of Columbia Brownfield Revitalization Act of 2000, as amended (D.C. Official Code §§ 8-631 et seq).</p> <p><u>Changes on 11/17/2007:</u> Section O.4 is modified to allow a falling head infiltration test similar to that used by neighboring jurisdictions. The falling head test method was added to make infiltration tests easier to perform in the District. However, the other acceptable test methods report hydraulic conductivity, rather than infiltration rate, which is a better measure of a soil’s properties.</p> <p><u>Changes on 05/01/2014:</u> In the first bullet, remove “Well Permeameter Method (USBR 7300-89)” and replace with “Constant Head Bore-Hole Infiltration Tests” and a description of the related process and equipment. Remove the second bullet, “Tube Permeameter Method (ASTM D 2434).” In the third bullet, add a description of the Double-Ring Infiltrimeter test process. In the fourth bullet, remove</p>			

Description of Change	Page	Date Published	Type
<p>“recognized published” and replace with “peer reviewed.” After the list, add “All soil borings and test pits shall be properly backfilled after conclusion of tests.” These changes are needed to provide greater detail on constant head test methods and process, as requested by local geotechnical consulting practitioners.</p>			
<p>Section O.5 Saturated Hydraulic Conductivity Calculations</p> <p>Add the equation that must be used to convert the results of the falling head test to a hydraulic conductivity value.</p> <p><u>O.5 Saturated Hydraulic Conductivity Calculations</u></p> <p><u>To convert the field infiltration measurements to a saturated hydraulic conductivity value (K_{sat}), the following calculations must be performed.</u></p> $K_{sat} = \frac{\pi D}{11(t_2 - t_1)} \times \ln\left(\frac{H_1}{H_2}\right)$ <p><u>where:</u></p> <p><u>K_{sat} = saturated Hydraulic Conductivity (in/hr)</u> <u>D = casing Diameter (in) (minimum 4 inches)</u> <u>t_2 = recorded End Time of Test (hr)</u> <u>t_1 = recorded Beginning Time of Test (hr)</u> <u>H_1 = head in Casing Measured at Time t_1 (ft)</u> <u>H_2 = head in Casing Measured at Time t_2 (ft)</u></p> <p><u>Equation adapted by: U.S. Bureau of Reclamation in 1975 from Lambe and Whitman, 1969.</u></p> <p>Section O.5 is added to provide the calculation that must be used to determine the hydraulic conductivity from the falling head test. This equation provides equivalence between the falling head test and the other acceptable test methods.</p>	O-3	11/17/17	E
